

1. Exercise 6: Data Visualization “TASK 3: Advanced Dashboard” Truncated

Output/Warnings

Problem: I initially got an “error” in Task 3, and the output was being truncated, which made it difficult to identify the exact issue. It was fixed by the collab Gemini by adjusting the `sns.countplot`, `sns.boxplot`, and `sns.violinplot` functions to explicitly include `hue` and `legend=False` in order to handle Seaborn FutureWarning messages that were causing the truncation. The collab Gemini also temporarily added try-except blocks to check for Python exceptions, but it was later confirmed that the issue was caused by non-critical warnings rather than an actual code error. As a result, the plots for Task 3 are now generated successfully and displayed correctly without warnings.

2. Exercise 7: Integration Challenge – Initial Setup and Pandas FutureWarnings

Problem: In my initial code for Exercise 7, the scatter plot (Visualization 1) was using the raw age values for coloring instead of `age_group`, and the analysis paragraph still contained a placeholder for the highest CLV value. It was fixed by the collab Gemini by modifying the scatter plot to correctly use `age_group` for coloring and updating the analysis paragraph to dynamically insert the calculated highest CLV value. After these changes, I encountered another issue caused by Pandas FutureWarning messages related to groupby operations on categorical columns such as `age_group`. The collab Gemini fixed this by explicitly adding `observed=False` to the groupby calls for `age_group_summary` and `avg_clv_by_age` to suppress the warnings. As a result, Exercise 7 is now fully completed, with all calculations, visualizations, and the analysis summary generated successfully without warnings or errors.
